Dynamic Dispatch

As we have discussed in class, the nature of dynamic dispatch makes the compiler does not know which member function to invoke until it generates the code. Before runtime, all the virtual function's address are stored inside a virtual method table waiting to be invoked, and the object, which contains the pointer to the virtual method table shall call the pointer to finish the implementation.

In the snippet I created, I built two objects a, and b which both contains two virtual functions ret() and ret1(). However, these two have different behaviors. In the main function, I created a "a1" object with type a and "a2" object with type b. Later I invoked the two member functions (ret() and ret1()) inside two objects.

From the assembly code compiled, I found that after the assembly has invoked the function to create two objects respectively, it then move the DWORD PTR [esp+24] to the register eax. As mentioned before, the address toward the virtual method table. Hence moving the pointer at esp+24 shall bring us to the virtual method table. Then it takes the pointer address of eax which is the address in the virtual method table that pointing toward the actual member function. In the end, it will take the address of the member function "mov eax, DWORD PTR [eax]" and call the function "call eax". When invoking the second function inside the object, it will do the same operation as before but when reaching the virtual method table, it will add "4" to the register eax since all member functions inside the virtual method table are located in order by 4 byte difference. When it tried to call a different object, it will then do the same process again with a virtual method table address stored in the object

```
1 //Yujian Li (yl7kd) 04/12/16 Section 102
2
3 #include <iostream>
4
5 using namespace std;
6
7 class a{
8 public:
9     virtual void ret() const {cout<<"I am a"<<endl;}
10    virtual void ret1() const {cout<<"I am 1"<<endl;}
11    virtual ~a(){}
12 };
13
14 class b:public a{
15 public:
16     virtual void ret() const {cout<<"I am b"<<endl;}
17     virtual void ret1() const {cout<<"I am 2"<<endl;}
18 };
19
20 int main(){
21     a *a1 = new a;
22     a *a2 = new b;
23
24     a1->ret();
25     a1->ret1();
26     a2->ret();
27     a2->ret1();
28     return 0;
29 }
```

```
246 mov DWORD PTR [esp], ebx
247 call _ZN1aC1Ev
248 mov DWORD PTR [esp+24], ebx
249 mov DWORD PTR [esp], 4
250 call _Znwj
251 mov ebx, eax
252 mov DWORD PTR [esp], ebx
253 call _ZN1bC1Ev
254 mov DWORD PTR [esp+28], ebx
255 mov eax, DWORD PTR [esp+24]
256 mov eax, DWORD PTR [eax]
257 mov eax, DWORD PTR [eax]
258 mov edx, DWORD PTR [esp+24]
259 mov DWORD PTR [esp], edx
260 call eax
261 mov eax, DWORD PTR [esp+24]
262 mov eax, DWORD PTR [eax]
263 add eax, 4
264 mov eax, DWORD PTR [eax]
265 mov edx, DWORD PTR [esp+24]
266 mov DWORD PTR [esp], edx
267 call eax
268 mov eax, DWORD PTR [esp+28]
269 mov eax, DWORD PTR [eax]
270 mov eax, DWORD PTR [eax]
271 mov edx, DWORD PTR [esp+28]
272 mov DWORD PTR [esp], edx
273 call eax
274 mov eax, DWORD PTR [esp+28]
275 mov eax, DWORD PTR [eax]
276 add eax, 4
277 mov eax, DWORD PTR [eax]
278 mov edx, DWORD PTR [esp+28]
279 mov DWORD PTR [esp], edx
```

(DWORD PTR [esp+24] for object a and DWORD PTR [esp+28] for object b]). As we have mentioned before, the calling process for dynamic dispatch is different from the previous method calling techniques since the method's name is never shown but represented by a pointer instead. Since the compiler will not know which function to invoke, it is important to use the virtual method table to point toward the actual method and connect with the actual object or it will be impossible for the code to know which method to invoke in the end.

Optimization

Compiling with -O2 flag shall give us an optimized version of the assembly code. In the second snippet I created, I compiled and generates its assembly with and without -O2 flag and then compare the result to see the specific optimizations it used.

The first optimizations I saw by comparison is the usage of registers instead of pointers. In the main functions, the unoptimized code on the left, it uses a lot of DWORD PTR of esp in order to perform operations. On the optimized code on the right; however, it pushes a new register ebx at the beginning of the code and uses it to throughout the assembly code to access variables and calculate. Similar case applied in the triple function where the optimized code used register esi at the beginning while the unoptimized code did not. Maximizing the register usage will help to accelerate the runtime of the program.

Secondly, the code uses a lot of complex instructions to simplify the amount of instructions to perform one certain operation. In the triple function section line 18 to 20, the original code was asked to do the additions with three registers. In the optimized code, it was simplified into one command “lea [eax+eax*2]” Merging three commands into one line will help the process of optimization.

As mentioned before, using “lea” allows “multiple math operations all in one instruction and it does not affect the flags register so you can put in in between one register being modified and a flags comparison jump on the next line.”

```

1 //Yujian Li 04/14/16 Section 102
2 main:
3 #include <iostream>
4 .cfi_startproc
5 using namespace std;
6 .cfi_def_cfa_offset 8
7 void triple(int a){
8     a=a*3;
9     cout<<a<<endl;
10 };
11
12 int main(){
13     for(int i=0;i<10;i++){
14         triple(i);
15     }
16     return 0;
17 }
18
19 .L3:
20     cmp DWORD PTR [esp+28], 9
21     jle .L4
22     mov eax, 0
23     leave
24 .cfi_restore 5
25
